## Configuration

YAM has a huge number of options, which can be set up in the configuration window. The program options are divided into sheets which can be selected by clicking on the corresponding word in the left part of the configuration window. There are also three menu items available.

### First Steps

This sheet contains some essential information needed for YAM to work.

#### Minimal configuration

##### Full Name

Your real name and surname. Please take care that this field is filled in correctly. DO NOT use quotation marks in your name.

Example: John Doe

##### E-mail address

This is your e-mail address, consisting of your <username>@<domainname>.

Example: jdoe@?

##### Mail server

The Internet address (hostname or IP) of your system's mail server. This server, which normally is a computer of your ISP (Internet Service Provider), must be capable of working with the POP3/SMTP protocol.

Example: mail.example.com

##### User name

The user name for logging into the mail server of your ISP.

Example: jdoe

##### Password

The password which is asked from you by your mail server. This password is possibly but not necessarily identical to the password you use to log in on your ISP, and is usually case sensitive.

Example: nguz56

#### Time zone

##### Timezone

The time and date displayed by YAM in the message list is always converted to your local time. This guarantees correct sorting of messages from all over the world sent out from different time zones. The time zone is part of the message's date and specifies the difference between local time and Greenwich Mean Time (GMT).

Examples: GMT+01:00 (for Central Europe), GMT 00:00 (for the U.K.), GMT-05:00 (for U.S. EST e.g. New York City)

Normally YAM will get the time zone from your Locale settings, thus this selector will be ghosted.

##### Add adjustment for daylight saving time

This option is to be activated during daylight saving time. By doing so, one hour will be added to the time zone value. YAM automatically changes to/from daylight saving time if the operating system support DST switching (e.g. AmigaOS4) or if a AutoDST tool like SetDST, FACTS or SummertimeGuard is installed. This is indicated by ghosting this checkbox.

Example: John Doe

#### TCP/IP

Here you can enter the information needed to actually send email, as well as define additional POP3 accounts.

### Send mail (SMTP)

Apart from the primary SMTP server already defined in the First steps section, you can set up an unlimited number of SMTP servers here; the names appear in the list on the left and clicking on a name brings up the relevant details on the right. Note that these accounts can be for the same user on a different server, or a different user on the same server. Either way, you can check for new mail with a single mouse click. Click on [New] to insert the data required for a new e-mail account. With [Delete] you can delete accounts.

#### Server

The Internet address of the system you're sending your mail to. This server, which usually is a computer of your ISP (Internet Service Provider), must be capable of processing the SMTP protocol.

Example: mail.example.com

#### Port

The port number of the SMTP service. The standard port is 25 for plain SMTP. In case of using SSL/TLS connections this port may also be 576 or 456.

Example: 25

#### SMTP server allows 8bit

Originally only the US-ASCII character set was allowed for use in e-mail, which meant that users were forced to use vowels (e.g., they had to use 'ae' instead of 'ä'). The reason for that was that many servers only processed the first 7 bits and simply cut off the 8th bit, crippling the e-mail while doing so. This problem was solved by introducing the MIME quoted-printable standard, which converts all 'unauthorized' characters to 7 bit before transfer and reconverts them to the original characters on delivery. Modern mail servers don't have problems with non-US-ASCII characters any more, so messages do not necessarily have to be converted. If you are absolutely sure that your server supports 8 bit transfers, you can switch this option on and save a few bits when transferring e-mails. The best way to find out if your mail server supports this is to write a message to yourself containing modified vowels and see what happens.

Example: Yes

#### Use SMTP AUTH

Enable this if you want to use SMTP Authentication, whereby YAM will request your mail server to use an extra authentication layer as documented in [RFC 2554](#). You will need to fill in another couple of UserID/Password fields in this case. If your SMTP server does not support SMTP AUTH, you will receive an error message when trying to send email. Ask your ISP if in doubt.

Example: No

#### Username

When using SMTP AUTH you can insert the user name for the SMTP authentication here. In most cases this will be identical to the username in your e-mail address. However, there are exceptions, so check the instructions from your ISP (YAM then constructs the full account name in the form <Username>@<server>).

Example: jdoe

#### Password

The password which has to be sent to the mail server at login time. You can leave this field empty for security reasons -- if you do, the password will be asked to you whenever you send new mails. Also, remember the password is case sensitive.

Example: nguz56

#### Use SMTP TLSv1/SSLv3

Enable this if your SMTP server supports TLSv1/SSLv3 secure connections. If enabled, YAM will connect via the AmiSSL library with the SMTP server and encrypts every transfer.

Example: No

## Receive mail (POP3)

Apart from the primary POP3 server already defined in the First steps section, you can set up an unlimited number of POP3 servers here; the names appear in the list on the left and clicking on a name brings up the relevant details on the right. Note that these accounts can be for the same user on a different server, or a different user on the same server. Either way, you can check for new mail with a single mouse click. Click on [New] to insert the data required for a new e-mail account. With [Delete] you can delete accounts.

### Server

The Internet address of the system you're sending your mail to. This server, which usually is a computer of your ISP (Internet Service Provider), must be capable of processing the POP3 protocol.

Example: pop.example.com

### Port

The port number of the POP3 service. The standard port is 110 for plain POP3. In case of using SSL/TLS connections this port may also be 995.

Example: 110

### Username

The user name for authentication against the specified POP server.. In most cases this will be identical to the username in your e-mail address. However, there are exceptions, so check the instructions from your ISP (YAM then constructs the full account name in the form <Username>@<server>).

Example: jdoe

### Password

The password which has to be sent to the mail server at login time. You can leave this field empty for security reasons -- if you do, the password will be asked to you whenever you send new mails. Also, remember the password is case sensitive.

Example: nguz56

### Active

Switch this option on to have the selected POP3 account checked for new mail whenever you use the Get new mail button in the toolbar, or the equivalent item in the "Folder" menu. If you don't want this email account to be checked automatically, switch this option off and use the menu item Folder/Check single account from the main window instead.

Example: Yes

### Use POP3 TLSv1/SSLv3

Activate this option to use SSL based encryption under the TLS protocol as described in [RFC 2595](#). This adds extra security to prevent the typical eavesdropping and hijacking attacks which POP is commonly subject to, and will use port 995 instead of the usual 110. The with STLS option will force the use of the POP3 STARTTLS extension, adding another layer of security to the communication, using again port 110. If your POP3 server doesn't support any of this, you will receive an error message when checking for new mail. Also, AmiSSL is required.

Example: Yes

### Login using APOP

Normally the Username and the password are transmitted as plain text when connecting to a POP3 server. Under certain circumstances, this could be a security risk, and for this reason modern POP3 servers support the APOP authentication, which transmits the username and password encrypted with a key which is delivered by the server. If your POP3 server does not support APOP you'll receive an error message when checking for new mail; in that case, switch this option off. Also note, that if your POP3 server supports TLS/SSL this should be preferred as it also transmits the email content encrypted rather than in plain text.

Example: No

### Delete mail on server

If this option is activated, new mail will be deleted after downloading it from the mail server. The messages will be deleted only after they have been successfully saved to your computer. If the POP3 account is used by several people, or if you'd like to access your account again later from another computer, this option can be deactivated.

Example Yes

## New mail

Controlling the way mail is downloaded.

## Download

### Pre-selection

After establishing a link with the POP3 server, a preselection window may open showing a list of all new mail in the POP3 mailbox. This allows you to decide whether to download, delete or leave a message on the server, according to its size, topic or sender. For pre-selection to work properly, the server must support the TOP command which most of them do.

*never*: pre-selection is deactivated

*large messages*: only messages bigger than a size defined by you will be displayed in pre-selection

*always*: every message will be displayed in pre-selection

*always, only sizes*: all messages will be displayed but only their sizes will be shown. The advantage of this method is that it is pretty fast.

Example: always

### Size limit

If pre-selection is activated, messages which exceed the size given here will be highlighted. This way you can avoid downloading messages with huge attachments. The size is given in kilobytes. If you don't want to use any limit, just insert '0'.

In everyday use, the settings 'pre-selection = large messages' and 'size limit=100 kB' have proved to be advantageous. With these settings, the pre-selection window will only appear if at least one of the new messages exceeds 100 kilobytes in size.

Example: 100

### Transfer window

Here you can decide if you want to see the transfer window while receiving or sending mail. With *automatic* it only opens if you manually initialize the transfer, staying closed while YAM automatically checks for new mail.

Example: never

### Avoid duplicates

If you choose not to have YAM delete the mail on the server after downloading, it will be downloaded again next time YAM gets your mail, so every message will appear twice in your mail folder. To prevent this, switch the Avoid duplicates option on -- as long as this option is activated, YAM will keep track of all your downloaded messages in the .uidl file and use special commands of the POP3 server to avoid downloading the same message twice. If the POP3 server supports these UIDL commands, this check will be done rather quickly. If the server doesn't support these commands, YAM will try to read the Message-ID using the TOP command instead of the UIDL commands. In case the mail server doesn't support any of these commands, this option must be turned off.

Example: Yes

### Update message status

If this option is activated, new messages in the 'Incoming' folder will be marked as 'unread' before downloading new mail. This way you can instantly recognize the new mail that was downloaded the last time you've fetched mail.

Example: Yes

## Automatic operation

Check for new mail every [xx] minutes

Here you can specify a time interval after which YAM will automatically recheck your mail server for new mail. To deactivate this option, simply select zero.

Example: 15 minutes

#### Download large messages

Whenever new mail is downloaded automatically (every x minutes or using ARexx), the selection window won't pop up since the user is likely to be working with another program at the time, or not in front of the computer at all. Mails exceeding the size limit won't be downloaded and will remain on the server if this option is not activated.

Example: No

### Notification

#### Requester

Once YAM has downloaded new mail, it will display a requester showing the number of new and deleted messages.

Example: Yes

#### Sound

Once YAM has downloaded new mail, it will play a sound file. The datatypes library is used for playing, so the sound file can be of any format (like AIFF or WAVE), as long as you have installed the appropriate datatypes. Click the small arrow (PLAY symbol) to test the sound.

Example: Data:Audio/Newmail.snd

#### Command

This is a program to be executed when new mail arrives. Insert the command as you'd do at a command line interface. If it is an Arexx script, you have to put the 'RX' command in front of the name of the script.

Example: RX PROGDIR:rexx/Newmail.YAM

### Filters

The purpose of a mail filter is to process mail according to criteria defined by the user. Whenever a mail matches a specified pattern, it can trigger certain actions. Applications for the use of filters include

- automatically moving mail from a mailing list to a specified folder
- automatic processing of incoming inquiries by sending pre-defined answers
- automatic deletion of unwanted spam (advertising by e-mail, a real pest nowadays)
- automatic re-directing of mails to another recipient.

You can define theoretically an unlimited number of filters. The list on the left shows the names of all the filters defined so far. Click on a name to bring up its details on the right, spread across three sheets -- Options, Comparison and Action. Click on [New] to create a new filter or use [Delete] to delete one. Filters are executed in top-to-bottom order, therefore you should place filters that delete or move messages at the bottom of the list.

### Options

#### Name

The filter's name is merely for recognition and not of any other use.

#### Remote filter

With a remote filter, new email can be checked on the POP3 server without being downloaded completely. The POP3 server must support the TOP command to be able to process this kind of filter. In contrast to 'normal' filters, only the contents of the e-mail headers can be searched for certain patterns. For obvious reasons, functions like forwarding or moving e-mails cannot be used with remote filters. In addition, if remote filters are activated they might slow down downloading e-mail, but they are handy and powerful if used with care.

#### Apply to new mail

Activate this option to have all new mail processed by this filter. Processing will start automatically after receiving new mail.

#### Apply to sent mail

Activate this option to have all sent mail processed by this filter. Processing will be initiated automatically after sending mail.

#### Apply on request

If this option is activated, the filtering process will be started by clicking on the Filter button in the main window or by choosing 'Filter' from the 'Folder' menu. This way you can also process old messages which do not necessarily have to be in the Incoming folder.

## Comparison

### Search in

Here you can define what part of the e-mail should be scanned for the search pattern. If you want a field of the message header to be searched, you can choose one from the list which appears when clicking on the cycle gadget, or select 'Other field' and insert the name of the header field into the text field on the right side of the cycle gadget. If 'Message body' is selected, the whole message -except for the headers- will be searched. Please note that this type of full text search may take quite a long time when big mails are processed (YAM will have to decode mails in MIME format).

Example: 'Other field: X-Mailer'

### Comparison

The instruction comprises the comparison operator and the search pattern.

YAM supports the following comparison operators:

- = the text which is compared must match the search pattern
- < the text must be "less" than the search pattern
- > the text must be "greater than" the search pattern
- <> the text must be different from the search pattern
- /N the text must match pattern contained in the file which is specified in the text field to the right side of the comparison cycle gadget. Instead of a search pattern itself, the name of a file has to be inserted here, containing one or several lines of search patterns. In this way it is possible to create a so-called 'Killfile' containing a list of e-mail addresses. Click on the page icon to edit the file.

Note that the comparison operators '<' and '>' work differently according to the type of field. YAM knows that a message size or date is numeric and sorts these in numerical order, but for fields such as "Subject:", alphanumeric order is used as in a telephone directory, so James < Jim and 12 < 2.

The search pattern may contain AmigaDOS wildcards such as ?, #?, (a|b) or [abc]. Please note that the search pattern [YAM]#? will filter all messages beginning with Y, A or M. For filtering mails coming from a mailing list (for example, a mailing list related to YAM), you'd better use the search pattern #?YAM#? or have the filter compare the Reply-To: field with the address of the mailing list.

Example: '= YAM 1.3.#?'

### Address/Name

If you make the filter search a header field containing an e-mail address, you can specify here whether the search pattern should be processed on the actual address (e.g. jdoe@?) or the author's name (e.g. 'John Doe').

### Case sensitive

Activate this option if you want the filtering process to distinguish between normal and capital letters.

### Substring search

If the search pattern consists of only a part of the header field which is to be searched through, you must activate this option - YAM will then complete the search pattern with #? internally.

It is possible to combine two search criteria. The cycle gadget lets you select how this is to be done:

*none* don't use a second criterion *and* both criteria must be satisfied *or* at least one of the two criteria must be met *exclusive or* either one or the other of the two criteria must apply, but not both

## Action

### Bounce

Activate this option to have mail matching the search criteria bounced to another recipient -- for instance, you might use this to automatically resend certain email to your mailbox at work.

The new recipient's e-mail address must be inserted into the text field next to the option.

Example: jdoe@?

### Forward

Activate this option when you want e-mail matching the search criteria to be forwarded to another person. The new recipient's e-mail address must be inserted into the text field next to the option.

### Reply

If this option is activated, YAM will send an automatic reply to any mail matching the search pattern. Enter the filename containing the auto-answer text into the text field next to this option.

Example: PROGDIR:Auto-Texts/Answer1.txt

### Execute

If this option is activated, an external program will be executed whenever an email matches the search criterion. YAM will send the path of the e-mail to the external program as a starting parameter. Insert the command line into the text field next to this option.

Please note that if you want an ARexx script to be executed, you will have to explicitly put the 'RX' command first.

Example: 'rx PROGDIR:Rexx/Subscribe.rexx'

### Play sound

Activate this option to have a sound played whenever a message matches the search pattern. The sound file name is to be inserted into the text field next to this option. YAM uses the datatypes library for playing the sound. Click the small arrow (PLAY symbol) to test the sound.

Example: Data:Audio/hatespam.wav

### Move

If you activate this option, YAM will move any email matching the search pattern to another folder. You can select the folder with the pop-up button.

### Delete

If this option is activated, all messages matching the search pattern will be deleted. (You probably guessed that... 😊)

### Don't download

If this option is activated, any message matching the search pattern will not be downloaded from the mail server. You can use a remote filter together with this option if several people share the same POP3 account.

## Spam

Setup of the spam filter.

Activate spam filter

Activates the spam filter, believe it or not 😊

Reset Spam training data

Resets the Spam training data. Should only be necessary in rare circumstances.

Check new mail for spam content

Automatically checks new mail for spam content.

Addressbook whitelisted

If a mail has an From: address that exist in your addressbook, it will never be considered as spam.

Mark mail as spam when moved to Spam folder

Any mail that is manually moved to the Spam folder are automatically marked as spam.

Mark new spam as read

This option will automatically mark new spam mails as read.

Move 'Not Spam' back to 'Incoming'

Will move mails that has been wrongfully detected as spam or mails that have manually been marked as 'Not Spam' back to 'Incoming' folder.

Apply filters

Applies all your defined filters to mail that is moved back to the 'Incoming' folder.

## Read

Layout options

### Message header layout

Header

If 'full' is selected, all the headers will be displayed. Select 'none' if you don't want to see any header. When you switch to 'selected', you can specify yourself which header fields should be visible in the Read window. For specifying the fields you can use any AmigaDOS pattern. The FROM, TO, DATE and SUBJECT fields are displayed by default. The header layout can also be changed (temporarily) in the Read window itself.

Example: '(From|Subject|Date|X-Mailer)'

Sender info

If a mail's sender is found in YAM's address book, YAM can display additional information in the header part of the Read window. If 'data only' is selected, YAM will show some information such as the name, date of birth, snail mail address, description, etc. as found in the address book for this entry. Select 'data and image' to make YAM display a picture of the sender (of course there's got to be one in the address book 😊) in addition to the other data.

Wrap headers

Choose whether to show long headers on one line or to break them on two or more. In the first case, you will need to use the horizontal scrollbar in order to see all the information.

### Message body layout

Separate sig.

It has become a custom to separate the signature from the text of an e-mail using two dashes and a space. If you don't like this kind of separation, you can define another here. Apart from the setting 'two dashes' you can select between 'separator bar', 'blank line' or even 'no signature' to have no signature at all.

Colored text

Text passages embedded in # characters will be highlighted by YAM in a special color both in the internal editor and in the Read window. Here you can define the color used for that purpose.

#### Old quotes

Select here the color used for the several levels of quoting.

#### Use fixed font

It often makes more sense to use a non-proportional font to read messages, since the layout of any tables will be distorted when using proportional fonts. Don't forget to specify the font of your choice in the 'TextEditor' module of YAM's MUI settings, under 'Fonts/fixed'.

#### Display all texts

If this option is activated and the message contains attachments, not only the actual body of the message will be displayed, but also those attachments themselves, as long as they are of the 'text' type.

#### Text styles

YAM uses the characters '\_', '/', '\*' and '#' to indicate underlined, italic, bold and colored text. For certain special documents, as it is the case with source code, this can make things difficult because some characters are suppressed. So you have the option of switching the rendering of text styles on or off.

### Other options

#### Multiple windows

With this option selected, each message which you choose to read will open its own Read window.

### Write

Headers, stock phrases and editor settings

#### Message Header

##### Reply to

Normally this field should remain empty. The default Reply-To address is your e-mail address. If you want to use a different address, then (AND ONLY THEN!!) you should insert that address here. Alternatively, you can use the pop-up button to open the address book window, and then drag an entry from there into this field.

Example: jdoe@?

##### Organization

If you want the name of your organization, school, club or whatever to appear in a header of your message, insert it here.

Example: Doe Donut Production Ltd.

##### Extra headers

If for some reason you need to add one or more special extra lines to the headers of your mail, you can insert these header lines here. If you would like to insert several lines, separate them by inserting '\n'.

PLEASE DON'T use this feature unless you have enough knowledge of the structure of Internet email.

Example: 'Content-Language: uk\nKeywords: Pattern, YAM, Internet'

### Message Body

#### Welcome phrase

YAM will insert this text at the beginning of every new message you write (except for answers and forwarded messages). You can define a line break by inserting '\n'.

Example: 'Hello,\n'

#### Closing phrase

This text will be inserted at the end of every new message you write, just before the signature separator. You can insert a line break with `\n`.

Example: `'Kind regards\n\nJohn Doe'`

#### Warn when there's an empty subject line

Activate this option to let YAM warn you any time you try to send an email with an empty subject line. This may be the case when sending email to mailing list managers and other automated services, but it is generally considered as bad taste to use an empty subject line when posting to a mailing list. If you seldom use empty subject lines or you use to forget to fill in this field, you might want to use this option.

## Editor

#### Word wrap

When you save a newly written message, it will be formatted to make sure that no line has more characters than the value specified here. You can also decide whether YAM will insert line breaks as you type or if this should be postponed until you send the message. In the first case, the internal editor will insert line break codes while you're typing the message. This way you avoid unwanted surprises when the text is formatted later on saving the message, but on the other hand, any subsequent insertion or deletion of text might be a little less comfortable.

Example: 76

#### External editor

If you do not like the internal editor and wish to use another one (thereby forgoing automatic spell checking, text styles and glossary), you can insert its name here. Remember to insert the full path for the editor, and maybe an appropriate command line option.

Examples: `'C:Ed'`

#### Launch immediately

Activate this option if you would like the external editor to be launched automatically as soon as you start creating a new message. By doing so you won't have to click on the [Editor] button in the Write window.

#### Email cache

YAM can cache on disk a certain number of the most recent recipients used when writing a new email, if those recipients aren't already in your address book. This may improve the performance of the automatic name completer, especially if your address book is rather brief and you often find yourself having to type your recipient's name and address.

If the hit ratio of the email cache is very low in your everyday use, you might want to turn it off completely by selecting zero mails.

## Reply

#### Options for quoting messages

## Forwarding

#### Initial phrase

This text will be added at the beginning of the original text of any message you forward. Click the pop-up button to select from a list of variables which can be inserted (for example `%r` stands for the name of the recipient, `%s` stands for the subject, etc.). When the text is inserted into the message, YAM replaces the variables with their respective values, taken from the forwarded message.

Example: `'* Forwarded message, originally by %n on %d: *\n'`

#### Terminating phrase

This text will be inserted at the end of any forwarded message, but before the greetings phrase. Click the pop-up button to select a variable from the list (for subject, date, sender, etc.).

Example: `'* End of forwarded message *\n'`

## Replying

#### Default reply phrase

When you reply to a message, YAM can automatically insert three different phrases in the new message: greetings (Open), an introduction to the quoted message (Intro) and a closing phrase (Close). Use the cycle gadget to select one of these phrases and enter it in the field on the right. Click the pop-up button to select a variable from the list (for subject, date, sender, etc.).

Example: [Open] 'Hello %f,\n'

[Intro] 'On %d, you wrote:\n' [Close] 'Kind regards'

#### Alternative reply phrase

Communicating via Internet often means writing in another language. For that reason, YAM is capable of using an alternative reply phrase set, which will be used automatically whenever the recipient's address matches an user defined pattern. This way you can, for instance, use a German version of the reply phrase set for addresses in Germany, Austria and Switzerland, while using the English version for all other countries.

Example: [Open] 'Hallo %f,\n'

[Intro] 'Am %d schreibst Du:\n' [Close] 'Mit freundlichem Gruss'

#### Use with these domains

Whenever the recipient's address corresponds with this AmigaDOS pattern , the alternative reply phrases will be used.

Example: '#?.(de|ch|at)' (Addresses of countries with German mother tongue)

#### Mailing list reply phrase

To answer a message belonging to a mailing list, another set of phrases is available -- they will be used if the message that is being answered is stored in a folder for which mailing list support has been activated (see folder configuration ).

Example: [Open] 'Hi!\n'

[Intro] 'On %d, %n wrote:\n' [Close] 'Kind regards'

#### Quote message using

The character(s) specified in the editing field plus a space will be put in front of each line of the original message. Click the pop-up button to select a variable for the sender's initials.

Example: '%i>'

#### Quote external using

The character(s) specified in the editing field plus a space will be put in front of each line quoted from an external source, not necessarily related to e-mail. This is used when inserting or pasting text using the "alternate quoted" method.

Example: '|'

#### Quote empty lines

Usually, the quotation character is inserted at the beginning of empty lines contained in the quoted message. If for some reason you don't like this, just deactivate this option.

#### Verify recipient address

If this option is enabled, YAM will check if the sender and the return address are the same -- if the "From:" and the "Reply-To:" headers of the message are different, you will be asked to select whom to reply to. This way it is fairly easy to reply privately to a message from a mailing list.

#### Strip signature

Activate this option to avoid quoting the signature (since you'll delete the signature anyway in most cases). This option will work only when the signature in the quoted message is separated from the actual message by the standard '- ' separator, that is, two dashes AND a space.

## Signature

You can define and use one standard and upto two alternative signatures within YAM (e.g. one signature for private email and another one for business). Clicking on the cycle button in the upper left corner of the window you can display and edit the signatures in the small text editor window below.

#### Use signature

If this option is activated, a signature will be inserted at the end of each message you write.

#### Edit in external editor

Click this button to open the external editor you have defined in Configuration/Write/External editor to edit the signature currently selected.

#### Insert random tagline

Click this button to insert the '%t' variable at the actual cursor position in the editor. When processing a new message, YAM will replace this variable with a random tagline from the taglines file.

#### Insert ENV:Signature

Click this button to insert the variable '%e' at the current cursor position in the editor. YAM will replace this variable with the contents of the 'SIGNATURE' environment variable while creating a new message. This way it is possible to have random values automatically inserted into the signature, like the date, the actual temperature, the time, your weight or whatever...

#### Tagline file

The tagline database contains taglines, little poems or other very important and witty pieces of wisdom which can be selected randomly and be inserted into the signature. There are collections of thousands of these taglines on Aminet.

Example: 'PROGDIR:taglines'

#### Tagline separator

Since a tagline can consist of several actual lines, the single entries in the tagline file have to be separated from each other. Insert the string that is used for separating one tagline from another in your tagline file into this text field.

Example: '%%'

## Lists

Columns, sizes, time unit, context menus

### Field settings

Folder list, Message list

Select the items you want to see in these lists.

As of YAM 2.4, you can also have a context menu for both the folder and message lists.

### General settings

Use fixed font

It often makes more sense to use a non-proportional font since the display might become distorted with proportional fonts. Don't forget to specify the font of your choice in the 'TextEditor' module of YAM's MUI settings, under 'Fonts/fixed'.

Time in Swatch Beats

Enable this option to display the time in Swatch Beats instead of the hours:minutes format. This revolutionary unit of time, invented by Swatch, a Swiss watch manufacturer, divides the day in 1000 beats and abolishes the different time zones. The meridian is Biel, a town located in Switzerland.

Size format

This setting allows you to select the exact format of the sizes given in the message and folder lists, as well as the preselection window.

## Status bar

### Position

Allows you to select the position of the status bar, or even disable it completely.

Example: Top

### Label

The contents of the status bar. Use the pop-up button at the right to select a variable for new, unread, etc. messages.

Example: '- Total: %t New: %n Unread: %u'

## Security

### Encrypting mails with PGP

#### PGP

##### PGP's directory

The famous (some people and authorities might even say notorious) programme PGP (Pretty Good Privacy) by Philip Zimmermann is used for encrypting, decrypting and digitally 'signing' messages. Please install PGP as described in PGP's manual and insert the full directory path of the PGP executable here. YAM recognizes automatically if you're using version 2.6 or 5.x.

Example: 'Work:Programs/PGP/bin/'

##### Your PGP key ID

If you want to sign messages with PGP, YAM needs the shortcut of your secret PGP key. Click on the pop-up button and select your key. If YAM cannot find your PGP key, then either PGP is not installed correctly on your system, or you've specified the wrong path for the PGP executable.

Example: 0x70804A7B

##### Encrypt to self

Encrypting messages for a certain recipient has one disadvantage: you cannot read or edit the message any more after encryption. Activate this option to be able to read the message after encryption. YAM will enable you to do so by simply encrypting the mail using the recipient's key as well as your own.

## Log files

### Log file path

YAM will save the log files to the path specified here. The format of log files is explained in the Reference chapter.

### Split log file

Switch this option on if you want YAM to create a new log file each month. To distinguish the different files that will be created, YAM includes the date in the log file name, e.g. YAM-Jan98.log. If you'd like one big single log file, just leave this option deactivated.

### Mode

If you are not interested in having log files at all, select 'none'. Select 'normal' to have only the important events like receiving/sending mail recorded. In 'verbose' mode, YAM will log every transferred e-mail in detail.

### Log all events

Deactivate this option if you're only interested in logging events having to do with the mail transfer (sending/receiving).

## Start/Quit

### Options for actions at start up and termination

**On program startup**

## Load all folders

If you have many voluminous archive folders, you can increase YAM's starting speed by deactivating this option. Furthermore, deactivating this option will save memory, because only the index files of the system folders will be loaded on startup -- the index files of the user-defined folders will be loaded only when they are needed.

## Mark new mail as unread

Switch this option on to mark all new messages as "unread" on startup.

## Delete old mail

In the case that you have defined a maximum age for specific folders, YAM will delete all messages exceeding this age before actually quitting if this option is activated.

## Remove deleted mail

Switch this on to make YAM empty the 'Deleted' folder on startup.

## Check birthdates

Switch this option on to make YAM search the address book on startup for people whose birthday is today. This way you can send your congratulations at once, in case it's the birthday of one of your pals (or maybe even business partners). When run from a shell, the NOCHECK switch prevents this check from being done.

## Send mail in outgoing queue

If this option is activated, YAM will search the Outgoing folder for messages to send on startup and ask you if you'd like to send them. Please note that this will work only if a TCP/IP stack has been loaded previously. You can temporarily stop YAM from doing so by starting YAM from a shell with the NOCHECK switch.

## Download new mail

If this option is activated (and there's already a TCP/IP stack running on your system), YAM will check the mail server for new messages on startup. You can temporarily stop YAM from doing so by starting YAM from a shell with the NOCHECK switch.

**On program termination**

## Send mail in outgoing queue

Activate this option to make YAM look for ready to send messages in the Outgoing folder before actually ending the program. If it's activated, YAM will ask you if you'd like to send those messages before quitting. (Of course it will do so only if there are actually any messages in the Outgoing folder.)

## Delete old mail

In the case that you have defined a maximum age for specific folders, YAM will delete all messages exceeding this age before actually quitting if this option is activated.

## Remove deleted mail

Switch this on to make YAM empty the 'Deleted' folder when closing down.

**MIME**

Configure MIME viewers for attachments.

**MIME viewers**

The program selected by default to display attachments is MultiView. Messages in MIME format contain a field called Content-Type in which the type of the encoded file is specified. You can define a different program to process every single type of file. This is important for users who do not want to use MultiView for processing images and sound files, or for processing file types not yet supported by datatypes. Click New to configure a display program, or

use Delete to delete an entry. In addition, new file types defined here are also taken into account when composing a new message. For instance, if a new attachment type "application/pgs" is defined for filenames ending in ".pgs", YAM will automatically use this MIME type when attaching files that bear this extension.

#### Attachment type

This is the type of the actual entry, and corresponds to the Content-Type field contained in the message. You can select one from the pop-up list or use AmigaDOS wildcards, e.g. 'image/#?' to use the programme for a whole class of file types.

Example: 'image/jpeg'

#### Extension

Filename extension for the file type. This extension allows YAM to assign the correct "Content-Type:" field for a file.

Example: 'jpg jpeg jfif'

#### Viewer

Choose the program you'd like to use to display the attachment. Do not forget to insert a "%" into the command line, which will be replaced by the filename when processing.

Example: 'TOOLS:Gfx/ViewJPG "%s"'

#### Default viewer

This viewer will be used if the attachment doesn't match any of the user defined types (see above).

Example: 'SYS:Utilities/MultiView "%s" SCREEN'

#### Identify binary attachments

Some mail clients always use application/octet-stream as the "Content-Type:" field for binary attachments. To still show such attachments with the correct program, YAM can search the viewer list based on the file name extension of the attached file (see Extension above).

### Paths

#### Decode files to

This is the pre-selected directory to decode attachments into.

Example: Work:Data/In

#### Attach files from

Whenever you want to attach a file to a new message, YAM will look for it at this position first.

Example: Work:Data/Out
